MySQL Workbench Screenshots – Headings and Explanations

Data Analytics | Module-End Assignment 3

The screenshots below are reproduced from the supplied Word document and arranged one per page with a related heading and explanation.

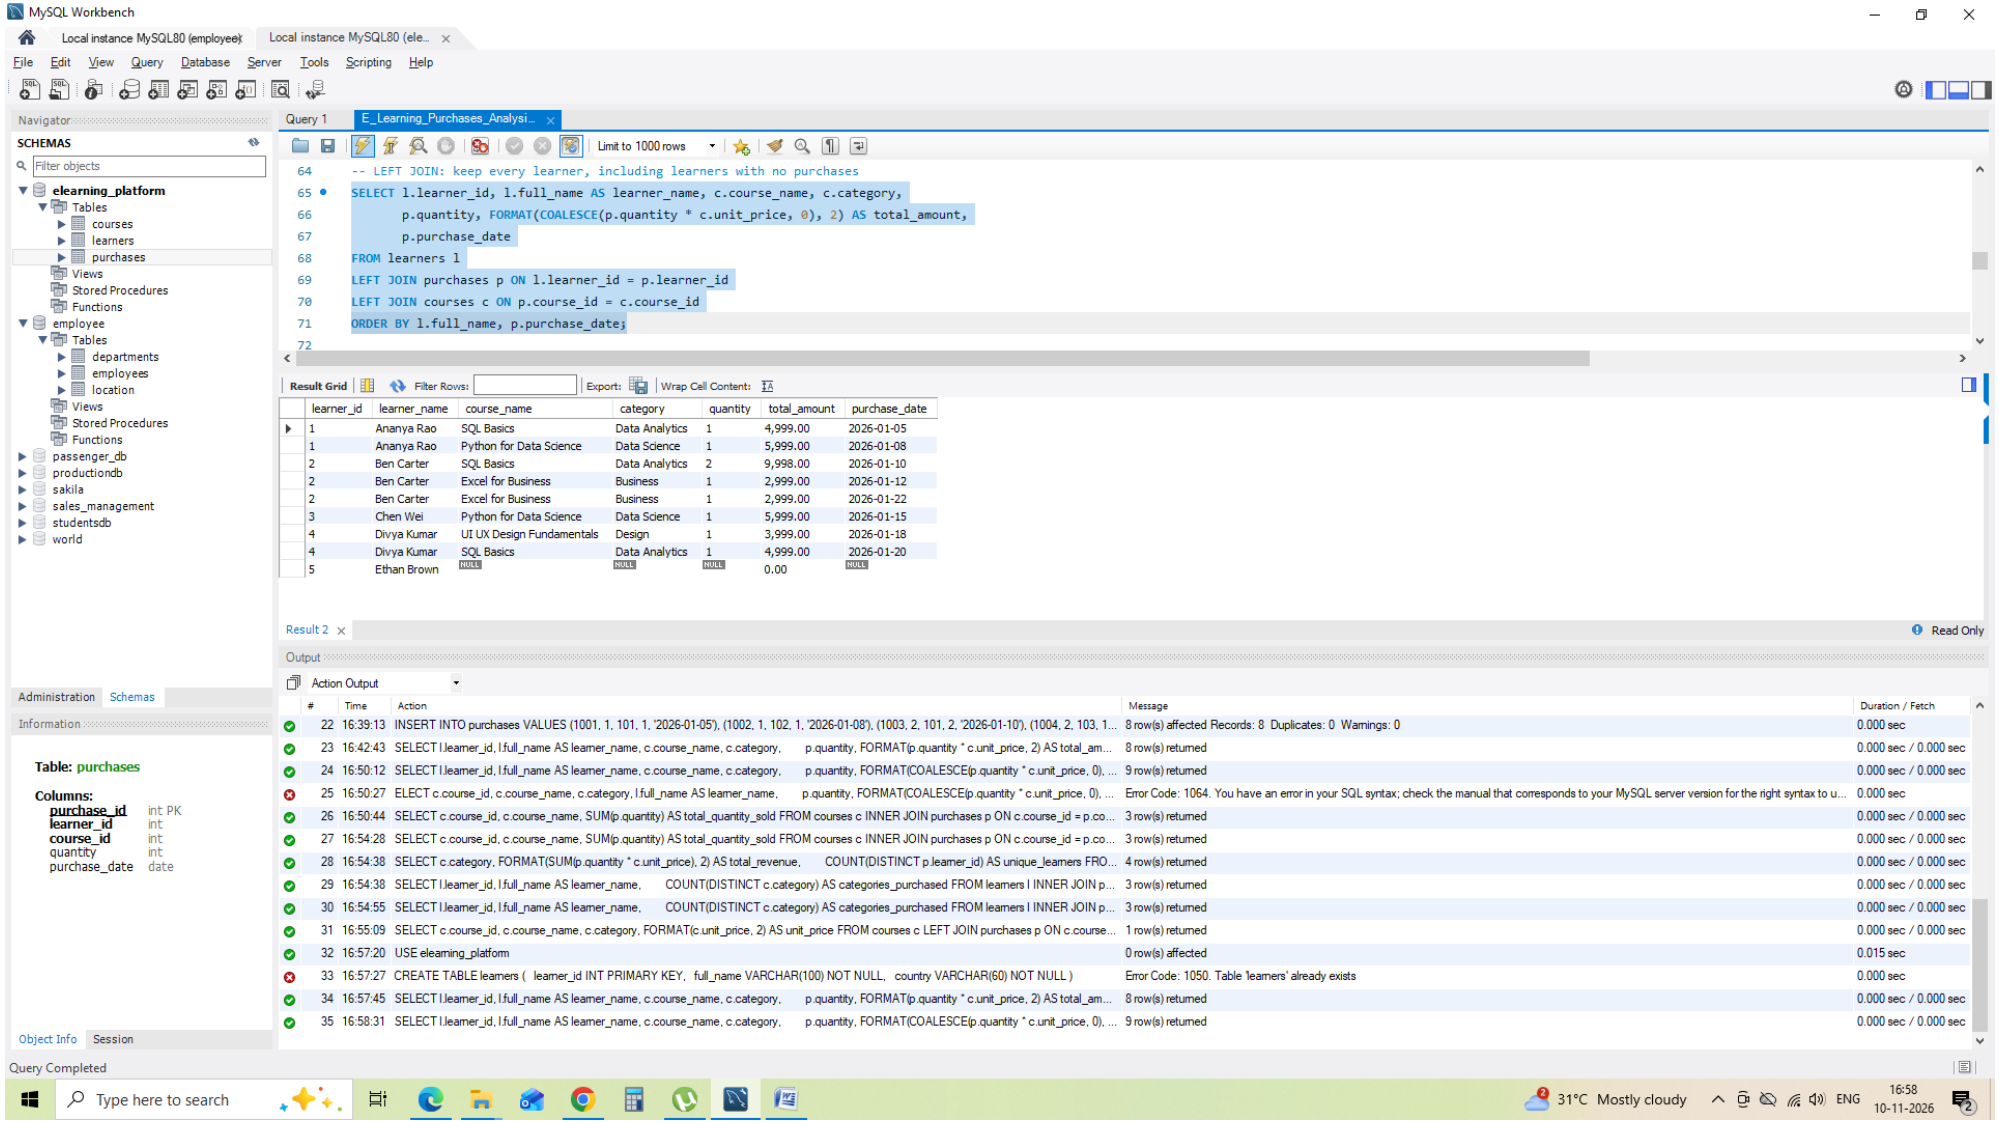

1. Database setup and initial SQL execution

This screenshot records a MySQL Workbench session with SQL statements selected in the editor and their execution output below. The output area helps confirm whether the statements ran successfully. Review the selected statements before moving to the next project step.

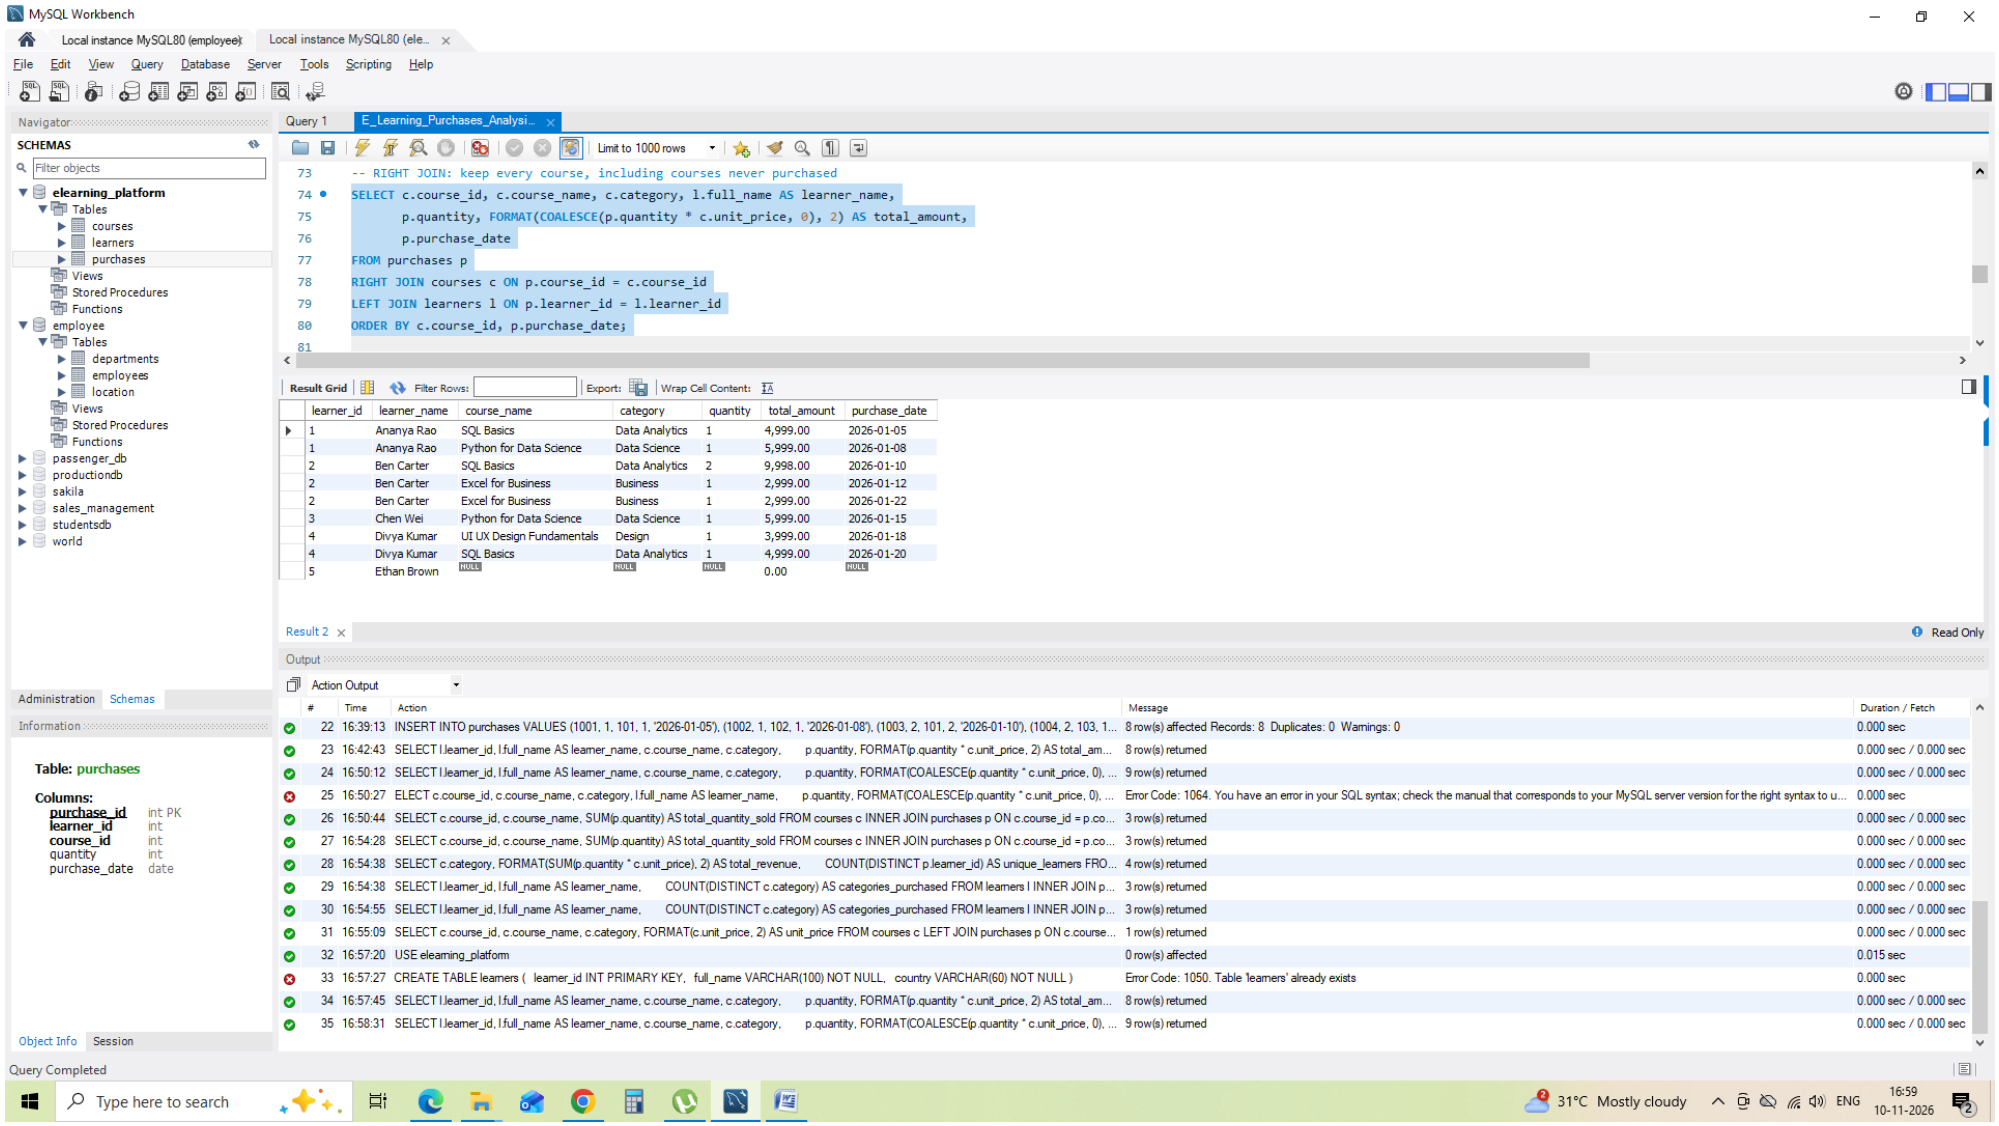

2. SQL query execution – learner and course data

The SQL editor shows the query being run, while the result grid displays the returned records. Use the result columns to check that learner and course information is being retrieved and presented in a readable format.

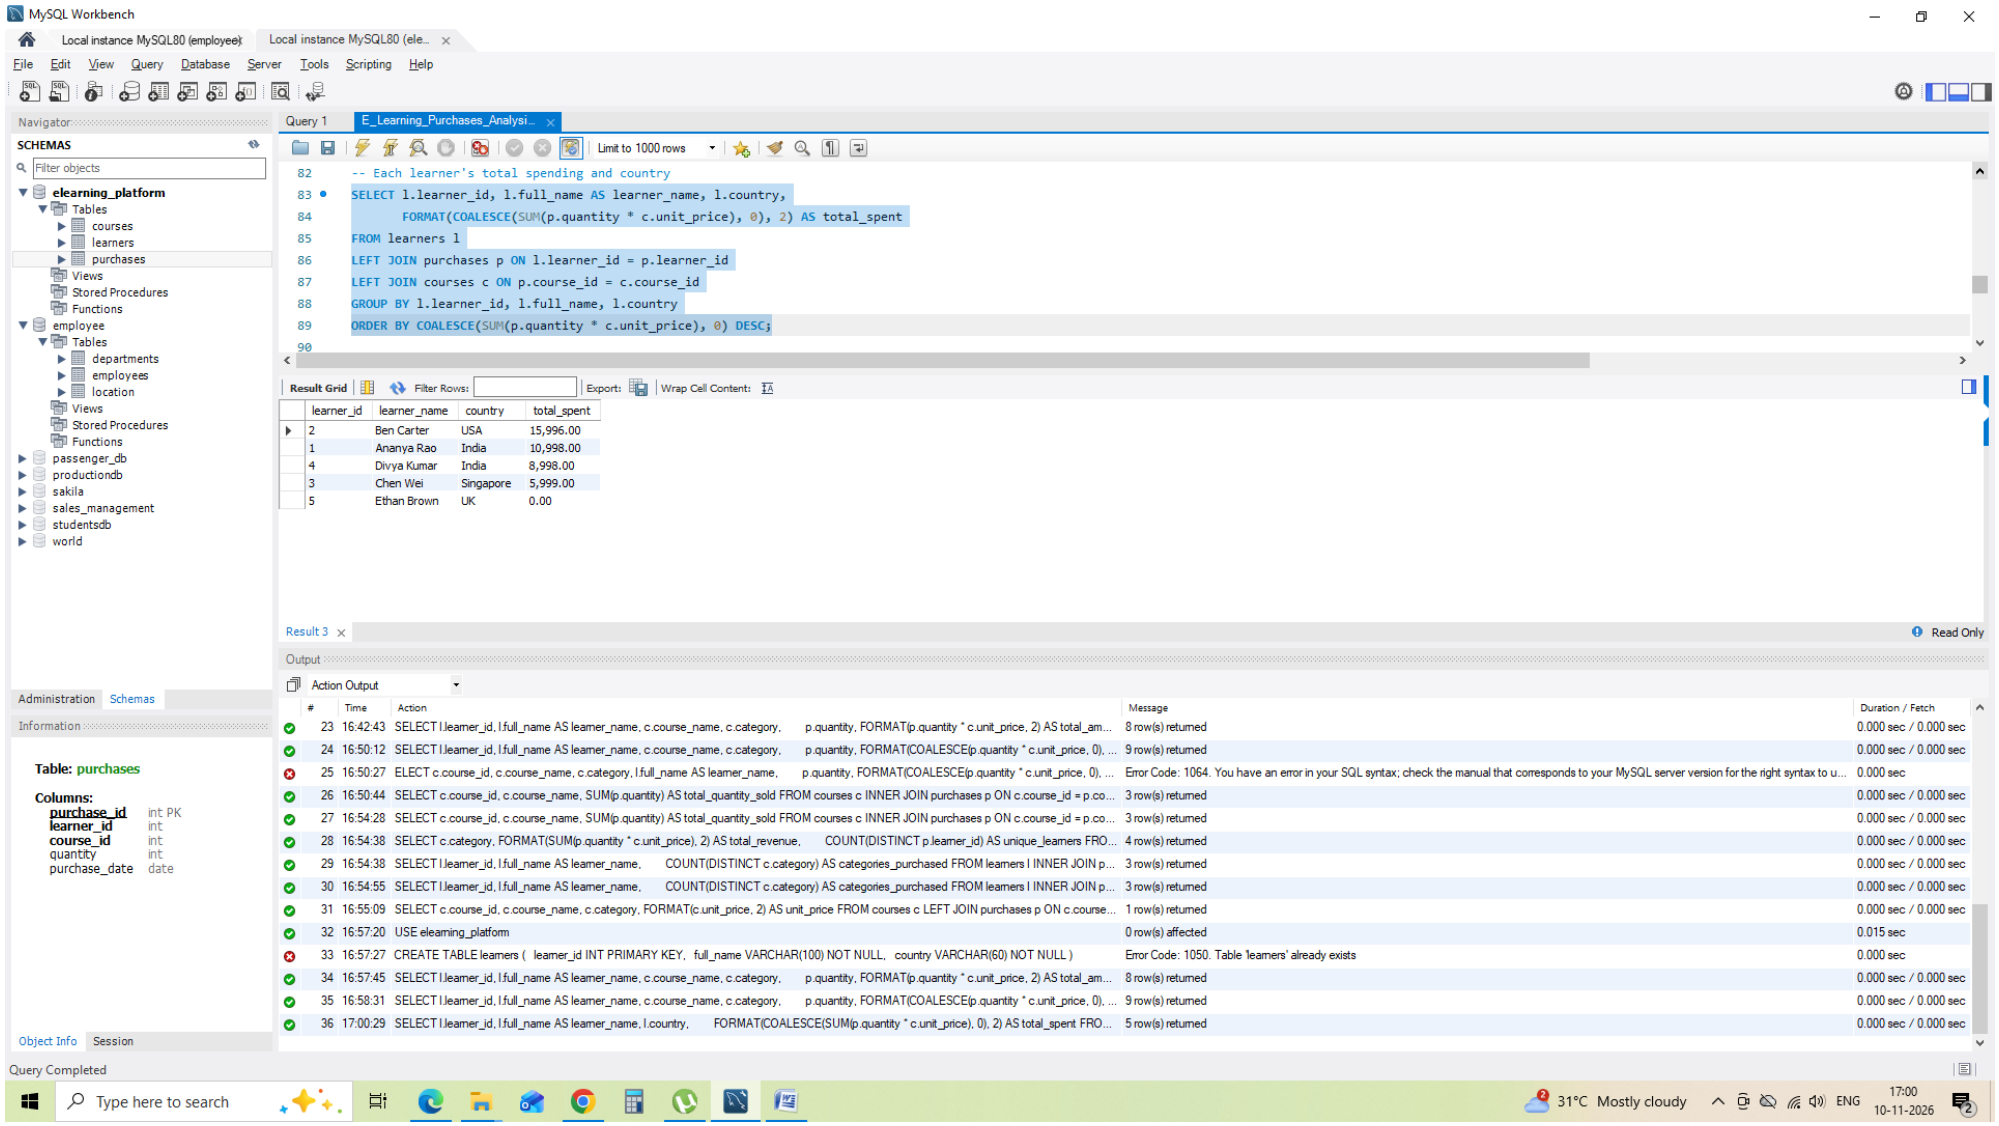

3. Purchase data exploration

This Workbench view shows a query together with its result grid. The result can be used to inspect purchase-related records and verify that the selected fields and returned rows are consistent with the project dataset.

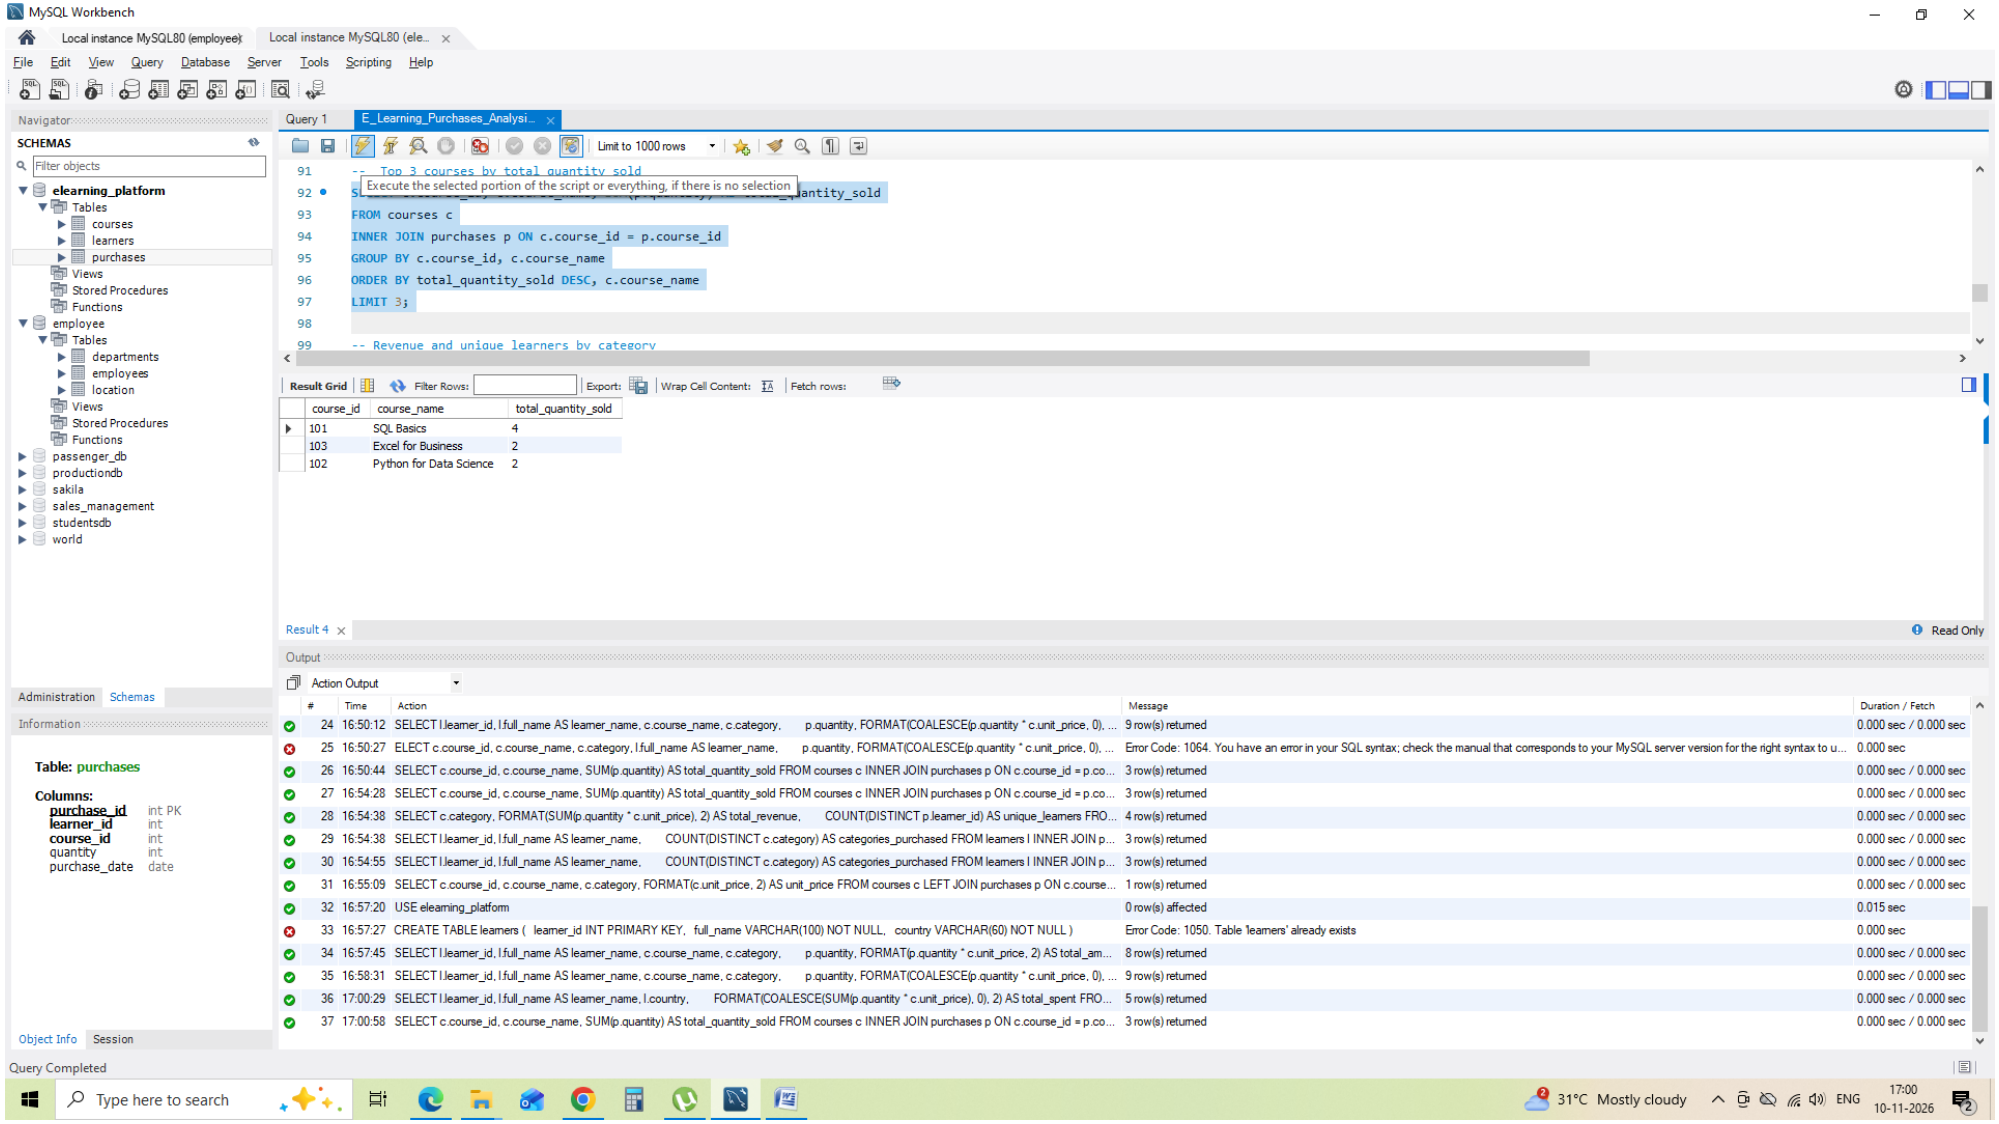

4. Join query results

The screenshot shows SQL execution and a tabular result. Join queries combine related records from the learners, courses and purchases tables using their matching key columns. Check that the returned rows contain the expected linked details.

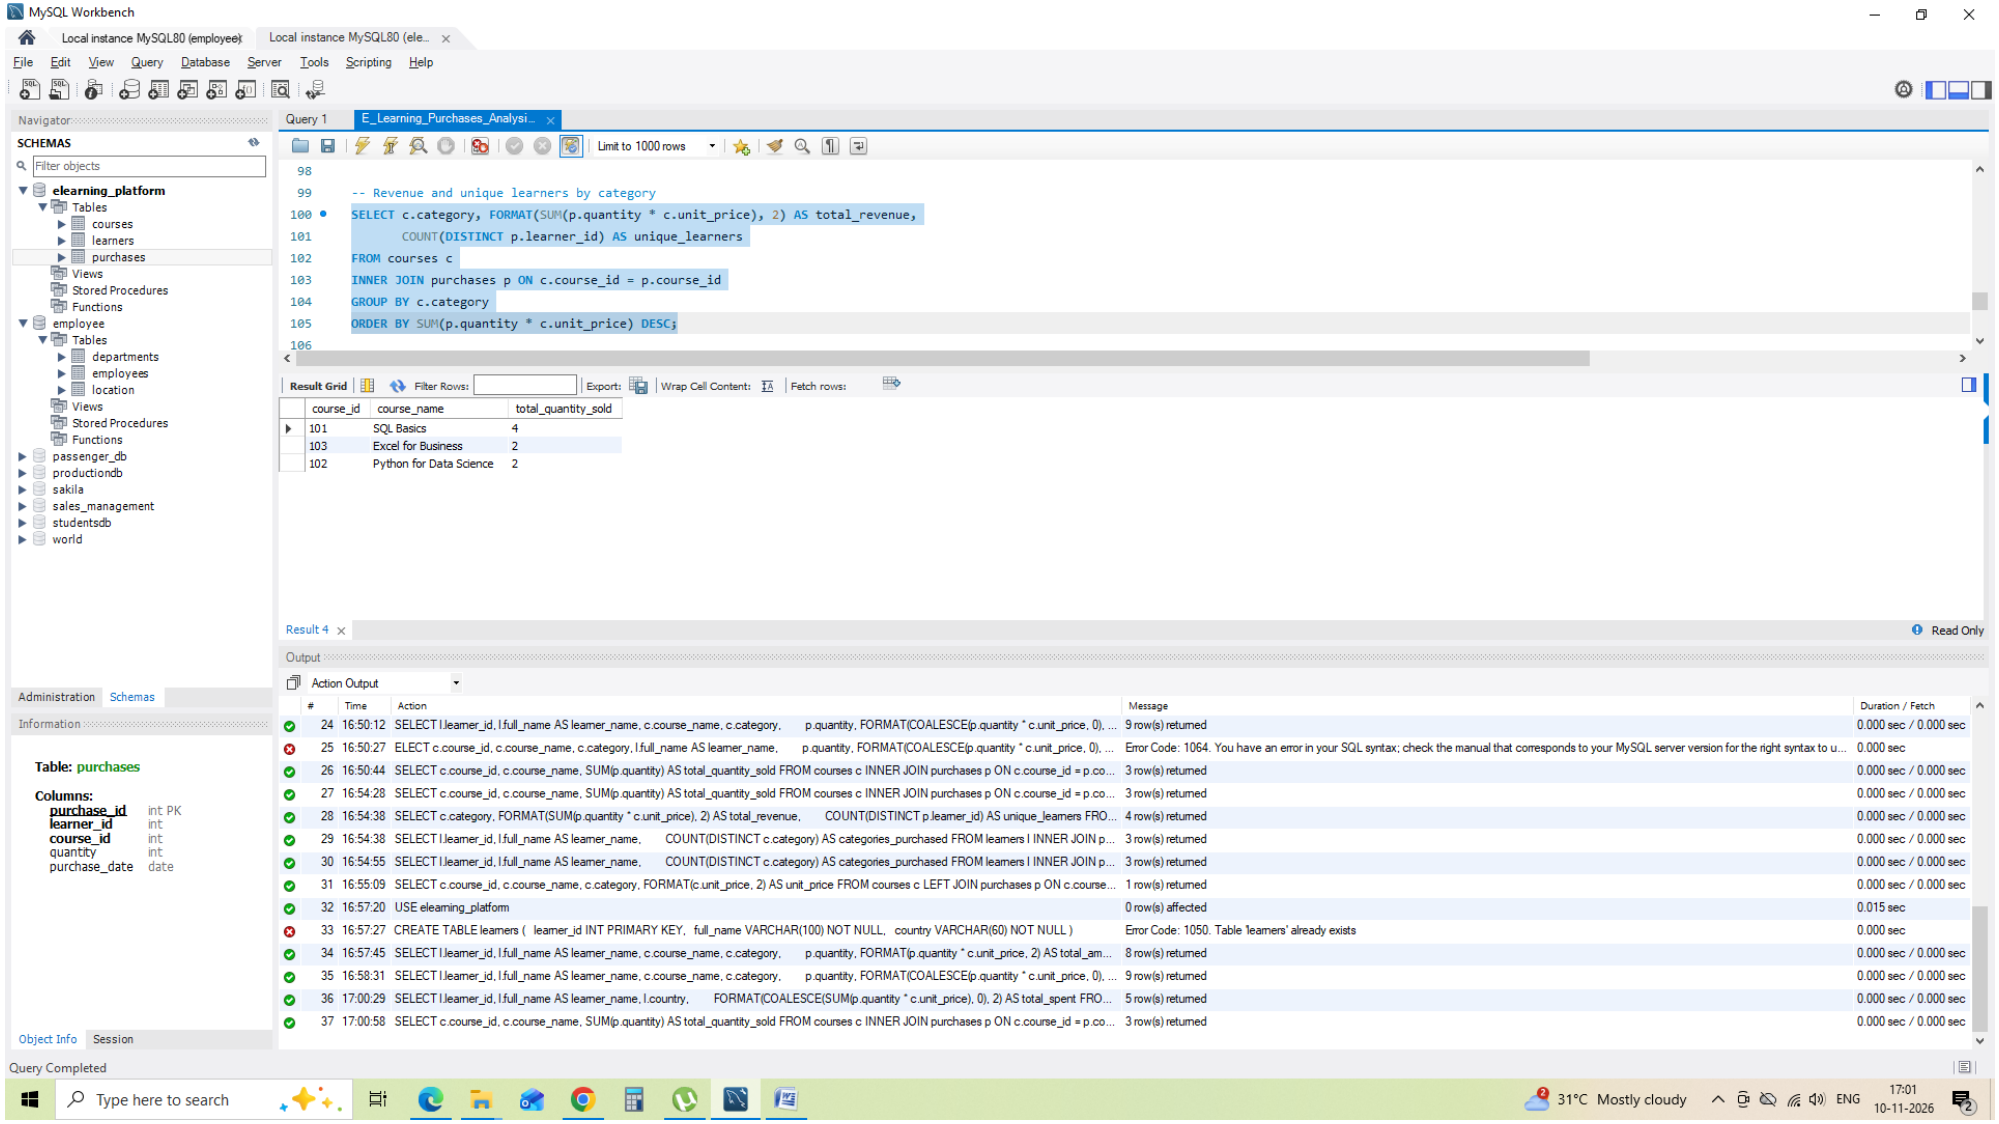

5. Analytical query – grouped results

The SQL statement and output grid provide evidence of an analytical query. Grouping and aggregate functions summarize purchase data, for example by learner, course or category. Check the column headings and totals in the result.

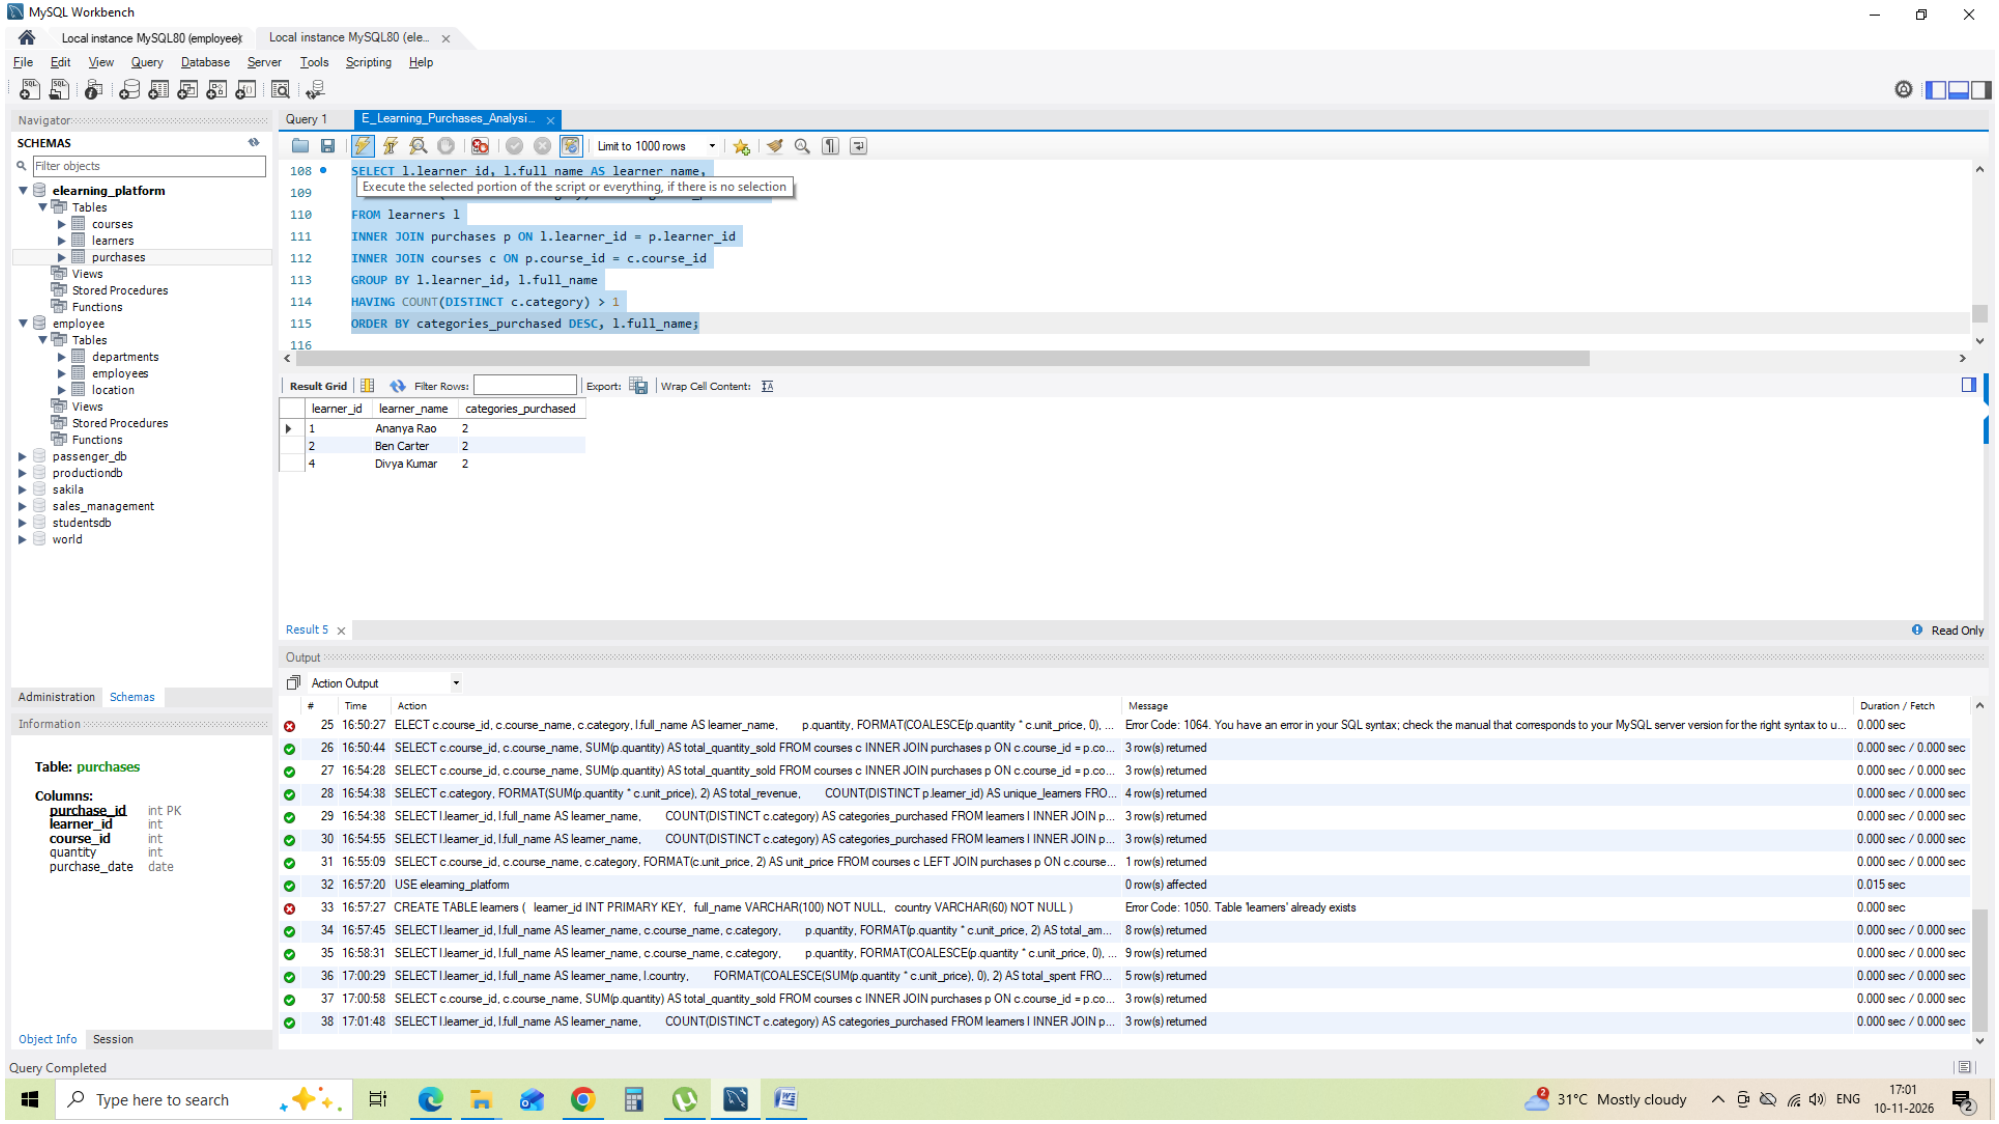

6. Analytical query – filtered results

This screenshot captures another query execution and its output. Filtering conditions restrict the rows or groups included in an analysis. Confirm that the result contains only records matching the query condition.

7. Course and purchase analysis

The editor and result area show a query being executed against the project database. Course-level analysis can be used to compare purchase activity and identify courses with higher or lower demand.

8. Final query execution and result verification

The final screenshot shows the MySQL Workbench query editor and output area. Use this result as a final check that the relevant SQL statement executes and that the displayed rows match the intended analysis.
